Abstract

Reducing system complexity and cost in synthesizing a sparse array antenna design is a challenging task for practical communication systems, such as radar systems and space communication. In this paper, a hybrid technique to synthesize a linear sparse array antenna design is described. This technique is developed using two methods. The first method is a combinatorial approach that applies cyclic difference sets (CDS) integers to significantly reduce the number of antenna elements. The approach and procedure used to apply the new CDS method to configure a linear sparse array, with significant reduction of the spatial antenna dimension, is described. The second method, applied to the array result of the first method, is amplitude tapering using a binomial array approach to reduce the sidelobes level (SLL). The simulation and measurement results of the sample sparse array design showed that the SLL was reduced in comparison to the sparse array design using only the combinatorial CDS method.

1. Introduction

Array antenna configurations are one of most useful antenna configurations in communication systems because they can provide a narrow beam width, variations in the beam pattern, directivity and high gain. High performance array antennas with very narrow beam widths and high directivity require large spatial apertures and a large number of antenna elements. These restrictions impact the antenna array sizing; thus, the communication system cost will be higher because of the many radio frequency (RF)/microwave components, filters and amplifiers that are required for each antenna element [1]. Therefore, reducing the number of antenna elements is a straightforward method to reduce the cost of a communication system.

In recent decades, antenna array designs have been developed with sparse element spacing characteristics. A sparse antenna array will achieve a desired radiation pattern with the minimum number of antenna elements, which is particularly useful in practical communication systems where the antenna weight and size are limited, such as in radar-phased antenna arrays, astronomy communications and satellite communications[1-2].

In the literature, various techniques have been proposed to configure sparse array antenna designs. Generally, there

are five sparse array antenna design methods that have been published; they can be classified as deterministic and generic algorithm methods [3-9], stochastic and probabilistic methods [10-12], general polynomial factorizations [13-15], combinatorial methods [16-18] and mutual coupling effects [19-21]. The combinatorial method, using cyclic difference sets (CDS), is a suitable design for a sparse array antenna with high efficiency, a simple process and minimal computation time compared with other sparse array methods.

The primary issue of the combinatorial CDS method is the sidelobes level (SLL) performance. When applying the CDS integer to the sparse array configuration, the performance of the SLL is lower when compared to that of the full array configuration. In some applications, such as a radar system, the SLL performance will impact the scanning process and the radar measurement system. Therefore, SLL performance improvement is an important issue in sparse array antenna design.

The classical solution to improve array performance is amplitude tapering to define the excitation coefficients for each antenna element. Some methods have been developed by antenna designers for the amplitude tapering technique, such as the binomial, Dolph-Chebyshev, Taylor and cosine approaches. Each method has different characteristics and advantages for array performance and configuration.

In this study, we developed a combined approach using the combinatorial CDS method with amplitude tapering using a binomial array. We chose a binomial array because the distribution of coefficient is in staircase form, based on Pascal's triangle, which matches with our new approach using CDS configuration element distribution. After the introduction in section 1, we describe the CDS integer approach and its application in the sparse array design in section 2. In section 3, we describe the hybrid technique, which applies amplitude tapering to the CDS configuration, and the proposed binomial array approach. In section 4, the simulation of a sample linear sparse array design to verify the proposed technique is presented, and the conclusion is presented in section 5.

2. New Combinatorial CDS Linier Sparse Array Design Approach

Difference sets are branches of the mathematical combinatorial theory, which are suitable for the design of a

sparse array antenna; this reduced a significant number of array elements [16-17]. By definition, a (V, K, Λ) difference set is a set of K unique integers based on V integers from all populations and Λ is possible unique differences appears sequence. In sparse array design, K unique integers can be used as a series of array elements based on V integers of full array element series.

From the set $D = \{d_0, d_1, \dots, d_{K-1}\}$, with $0 \leq d_i \leq (V - 1)$, such that for any integer $1 \leq \alpha \leq (V - 1)$,

$$\text{where: } d_i - d_j = \alpha \pmod{V}, i \neq j \quad (1)$$

These three parameters (V, K, Λ) are used to describe a difference set with only two independent parameters because there are $K(K - 1)$ possible difference $(d_i - d_j)$ with i not equal to j and because each $(V - 1)$ possible unique differences appears exactly Λ times.

The three CDS parameters will have the following relation:

$$K(K - 1) = \Lambda(V - 1) \quad (2)$$

Example CDS parameters and integers are

$D1 \{1,3,4,5,9\}$; where $V = 11, K = 5, \Lambda = 2$

$D2 \{1,2,4\}$; where $V = 7, K = 3, \Lambda = 1$

$D3 \{3,6,7,12,14\}$; where $V = 21, K = 5, \Lambda = 1$

$D4 \{0,1,2,4,5,10\}$; where $V = 15, K = 7, \Lambda = 3$

$D5 \{1,4,5,6,7,9,11,16,17\}$; where $V = 19, K = 9, \Lambda = 4$

The construction of a linear sparse array using CDS [16] is developed by using “one” and “zero” sequences following the CDS integers. From difference sets D , we may construct a sequence one and zero.

$$AV = \{a_i\} i = 0,1,2, \dots, V - 1 \quad (3)$$

where $a_j = 1$ if j is in D and $a_j = 0$ if j is not in D . For example, $D1\{1,3,4,5,9\}$ gives rise to $AV = \{01011100010\}$. The linear sparse array configuration can be constructed by starting with an empty lattice of element locations spaced $\lambda/2$ apart, placing an element at each location where a sequence has a “1” and skipping each location where the sequence has a “0” [16]. This approach can reduce the array by a significant number of elements from a full array configuration or minimize the array to approximately half of the number of elements (K/V) .

The challenge when using the CDS approach for sparse array design is reducing the high SLL as compared to a full array configuration [22]. In antenna array design, amplitude tapering is a classical solution to improve SLL performance by controlling amplitude excitation for each array element. The basic idea in amplitude tapering is the application of a normal distribution or a Gaussian distribution model to the power distribution. Following this principle, a new strategy for combinatorial CDS application to linear sparse array design is developed.

The new strategy for applying a CDS integer in the sparse array configuration is applied following the characteristic of the amplitude tapering distribution

function, which is the primary contribution of the radiation pattern emanating from the center of the array distribution (Gaussian distribution model). Using this approach, the new design procedure is as follows:

1. Split the full array configuration into two sides from the center of the array.
2. Define the array configuration as a representative of the V integer series for each side.
3. Apply the CDS K integer series for the sparse array configuration on each side.
4. Reduce the spatial antenna dimension for each side of the array configuration.

For example, a 32-element linear array microstrip antenna with inter-element spacing of $\lambda/2$ is reduced to a 16-element linear sparse array using our combinatorial CDS method. We choose a CDS $(15,7,3)$ for each side of the array configuration (16 elements per side). The sparse array element configuration following a CDS K -integer series places the element in the configuration of a D set integer $(0 1 2 4 5 8 10)$ element position, with one element in the center of the array for each side. The array configuration is shown in Fig. 1.

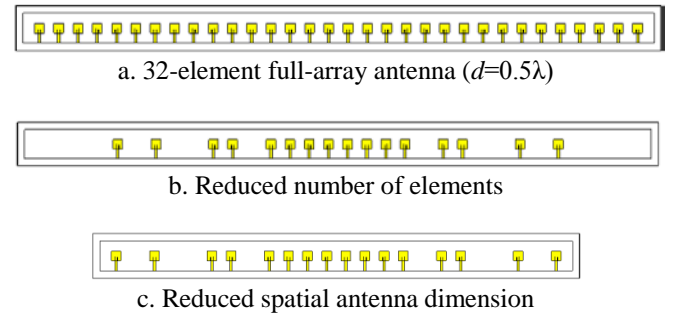

Figure 1: Design procedure of new CDS approach

3. Hybrid Technique Applying Binomial Amplitude Tapering

The proposed new configuration combinatorial CDS method for designing a linear sparse array antenna in the previous section is an effective method to reduce a significant number of elements, but this method still has the challenging issue of poor SLL performance. In the combinatorial CDS method, SLL performance was described using a relation between K and V [16, 22] as follows:

$$\text{PSL} = 10 \log \left[\frac{1}{K} \left(1 - \frac{K}{V} \right) \right] + 10 \log [0.8488 + 1.128 \log V] \text{dB} \quad (4)$$

Where PSL is peak SLL. The approximation is valid for $V > 50$ and $K < V/2$ [16, 23].

Using the approach in (4), the SLL performance in a combinatorial CDS is poor. In some applications, such as radar systems and satellite communication, the SLL performance is important for an accurate scanning result. To

b. 2D radiation pattern plot

Figure 3: Radiation performances of 16-element full-array antenna ($d=0.5\lambda$)

The design result of the 16-element full-array antenna was a gain of 18.8 dB with a half-power beam width of 4.5° and an SLL of -13.6 dB. The next step in designing a linear sparse array is splitting the configuration into two sides of eight elements each. CDS (7, 3, 1) is then applied to this split configuration as shown in Fig. 4a.

a. Reduced number of elements with CDS (7, 3, 1)

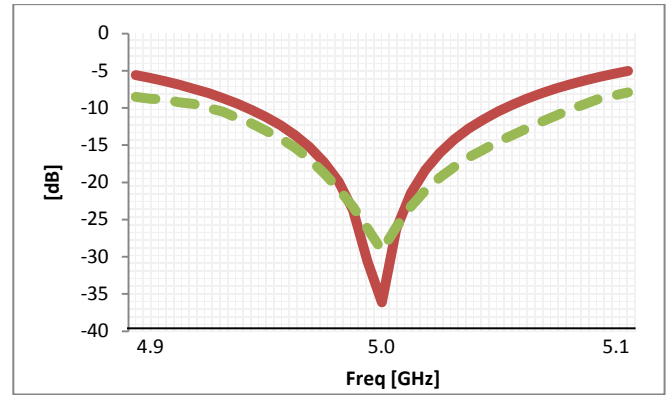

b. Reduced spatial antenna dimension

Figure 4: Design process of 8-element sparse array

In the next step of the sparse array design, the spatial dimension is reduced by decreasing the antenna length

(substrate) at the edges of both sides, resulting in the final configuration as shown in Fig. 4b. The simulation and measurement results of the s-parameter and the radiation performance are shown in Fig. 5.

a. S_{11}

b. 2D radiation pattern plot

Figure 5: Radiation performances of 8-element sparse array by applying CDS (7, 3, 1)

The simulation and measurement results show that the SLL of the radiation pattern linear sparse array using the CDS method is higher than that of the full-array configuration, as shown in Fig. 5. The SLL simulation is -12.0 dB with a 3 dB beam width of 7.8° and a gain of 16.1 dB.

The last step of the design process is to apply the amplitude tapering using a binomial array. For $N = 16$, the expansion of Pascal's triangle is 1, 15, 106, 462, 1386, 3038, 5014, 6463, 6463, 5014, 3038, 1386, 462, 106, 15, 1. The amplitude tapering coefficient for each element is shown in Table 1.

The coefficients and relative amplitude for each element listed in Table 1 is applied to the eight elements remaining after reduction by the CDS sparse configuration, i.e., element numbers 4, 6, 7, 8, 9, 10, 11 and 13.

Table 1: Amplitude Tapering Coefficients.

Element Number	Coefficient	Amplitude Attenuate (dB)
1	0.0001	-40.00
2	0.0020	-26.99
3	0.0200	-16.99
4	0.0700	-11.55
5	0.2100	-6.78
6	0.4700	-3.28
7	0.7800	-1.08
8	1.0000	0.00
9	1.0000	0.00
10	0.7800	-1.08
11	0.4700	-3.28
12	0.2100	-6.78
13	0.0700	-11.55
14	0.0200	-16.99
15	0.0020	-26.99
16	0.0001	-40.00

The simulation and measurement results of the proposed hybrid technique are shown in Fig. 6. The SLL simulation is -22.7 dB, a significant improvement over that of the combinatorial CDS linear sparse array. The implication of amplitude tapering is reduced directivity and a wider beam width, which are the compromises when the SLL is a priority in the antenna design requirements. The overall performance comparison is shown in Table 2.

Table 2: Performance Comparison of the hybrid technique for a 16-Element Array

No	Array Configuration	Elements & Aperture Length	Radiation Performances		
			Gain (dB)	3dB Beam width (°)	SLL (dB)
1	Full Array	16 (16.83λ)	18.8	4.5	-13.6
2	CDS Sparse Array	8 (10.78λ)	16.1	7.8	-12.0
3	Hybrid Technique Sparse Array	8 (10.78λ)	14.5	13.1	-22.7

Using the same design procedure, the proposed hybrid technique is applied to the design of a 32- and a 64-element full array antenna to a sparse array configuration. The performance results are shown in Tables 3 and 4.

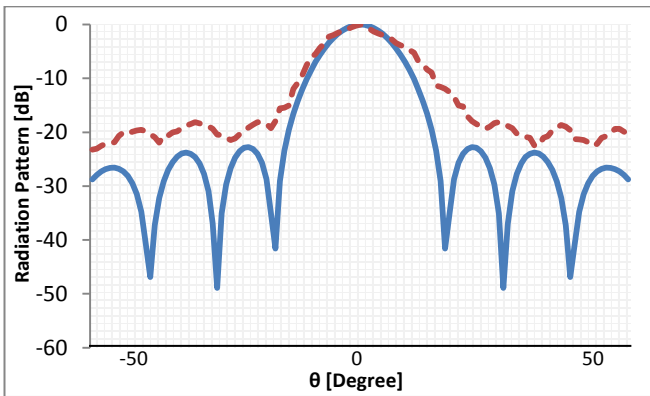

Table 3: Performance Comparison of the hybrid technique for a 32-Element Array

No	Array Configuration	Elements & Aperture Length	Radiation Performances		
			Gain (dB)	3dB Beam width (°)	SLL (dB)
1	Full Array	32 (32.94λ)	21.8	2.2	-13.6
2	CDS Sparse Array	16 (24.89λ)	19.2	3.2	-11.9
3	Hybrid Technique Sparse Array	16 (24.89λ)	16.1	8.8	-22.1

The overall performance comparison for larger number of elements is shown in Table 4. It is observed that the proposed hybrid technique has better efficiency for larger number of array (massively array) with significantly reduced number of array element and spatial antenna dimension. Furthermore, the simulation computation time speed proposed hybrid technique has better than CDS method and

a. S_{11}

b. 2D radiation pattern

Figure 6: Radiation performances of 8-element hybrid technique sparse array antenna.

full array configuration. Using CST software simulation for 16-element array, the proposed technique has 424,116 mesh cells compared to 532,980 mesh cells for CDS method and 741,636 mesh cells for full array configuration. It is shown significant reduced computation time speed for time domain solver.

Table 4: Performance Comparison of the hybrid technique for a 64-Element Array

No	Array Configuration	Elements & Aperture Length	Radiation Performances		
			Gain (dB)	3dB Beam width (°)	SLL (dB)
1	Full Array	64 (65.17 λ)	24.8	0.6	-23.2
2	CDS Sparse Array	32 (63.16 λ)	22.3	0.72	-10.9
3	Hybrid Technique Sparse Array	16 (26.9 λ)	17.3	6.6	-21.1

5. Conclusions

A new hybrid technique for the design of a linear sparse array antenna is described. The proposed method combines a new CDS approach with an amplitude tapering binomial array. The proposed new CDS configuration is a reduced spatial dimension array antenna that yields a significant reduction in the number of elements. The proposed hybrid technique for sparse array antenna design shows an improved SLL compared to both a combinatorial CDS linear sparse array antenna and a uniform amplitude full-array configuration. The hybrid design has a significantly reduced number of elements, antenna dimensions and computation time speed.
